

Intense Yellow

Intense yellow diamonds, often called “canary diamonds” for their rich hue, owe their color to the presence of nitrogen atoms within the carbon lattice, which absorb blue light and allow vibrant yellow to emerge.

Found in notable deposits in South Africa, Russia, Australia, and Canada, their saturation ranges from golden sunrise to deep saffron. Unlike paler yellow stones, intense yellow diamonds radiate a warmth that is both bold and uplifting, refracting light with the fire of a captured sunbeam.

The Story Behind Arun’s Fascination for the Diamond : Intense Yellow

For Arun, an intense yellow diamond is optimism made tangible. He is drawn to its unreserved brightness, the way it seems to carry daylight within itself regardless of the hour. To him, it’s not a gemstone that sits quietly, it declares joy, energy, and life.

When selecting intense yellow diamonds, Arun looks for stones with a pure, saturated hue that remains vivid in all lighting. He avoids overly green or brown undertones, seeking instead that electric golden tone that feels alive. Cut and proportion matter greatly to him, ensuring the stone throws back light as if it were scattering sunshine.

In an Arunashi creation, the intense yellow diamond becomes the heartbeat of the design, a burst of light around which everything else orbits. To Arun, it is proof that elegance doesn’t have to whisper; sometimes it can laugh, dance, and blaze its way into memory.
